

Laravel-Vue Skill Test

In Laravel:

Make a Laravel (v6) Application for API Handling where the API should be secured by specific APP_KEY & APP_SECRET for individual environment (eg. Android, ios, web).

Make user authentication system for that api with JSON Web Token (JWT) where the token should include the user information as the payload of that token and the token must be encrypted.

When the api request is made from the web you also verify that request with CSRF Token.

You must use Repository System (Dependency Injection) in user controller for the user crud.

In Vue:

Make a separate Vue-CLI application with only user authentication system which should use that Laravel API for authentication with CSRF protection.

Routes for vue app:

1. /login
2. /register
3. /dashboard (authenticated user)

When a user goes for /dashboard route, you must check if the user is authenticated before the vue instance is even created. For clarification, you must make a lifecycle hook which will be executed before the 'beforeCreate' hook, and you must check for user auth in that hook.

Also make a vue filter for showing user birthdate as '**Jan 01, 2000**' format.
